

NATURAL RESOURCES CONSERVATION SERVICE

CONSERVATION PRACTICE STANDARD

CLEARING AND SNAGGING

(Ft)

CODE 326

DEFINITION

Removing snags, drifts, or other obstructions from a channel.

PURPOSE

Reducing significant risks of “loss of life or property” by improving physical characteristics of a channel to:

- increase flow capacity;
- prevent bank erosion by eddies;
- reduce the formation of bars; or
- minimize blockages by debris and ice.

CONDITIONS WHERE PRACTICE APPLIES

Any channel or urban floodway where the removal of trees, brush, and other obstructions is needed to accomplish one or more of the listed purposes.

CRITERIA

Clearing and snagging measures shall be planned, designed, and constructed to comply with all Federal, State, and local laws and regulations.

Threatened and endangered species and their habitat shall not be permanently impacted by the use of this practice.

Clearing and snagging shall not be completed on any channel where significant channel erosion will occur, major impairment to the landscape resource quality is likely, or significant impairment to habitat for fish and wildlife will occur, unless needed restoration actions are included with the application of this practice.

The capacity of the channel, both before and after improvement, shall be determined using Manning’s Formula with applicable values of the retardance factor “n” from Supplement B to the National Engineering Handbook, Section 5 – Hydraulics, or similar source. The value of “n” used to determine channel capacity after improvement shall reflect the degree of natural changes and maintenance expected to occur in future years.

The area to be cleared and snagged shall include the perimeter of the channel, the flow area of the urban floodway, or both. Trees on the bank that are leaning over or other objects that may fall into the channel shall also be included. If root balls are still attached to the streambank, cut off the log 6 to 12 inches above the ground and leave the stump and root mass for bank stability.

Clearing and snagging shall be specified for other areas, including berms, for use as temporary disposal areas or travelways, or for other planned conservation uses where needed to implement this practice.

Clearing and snagging shall not impair channel stability. The criteria for determining channel stability shall comply with Conservation Practice Standard (582), Open Channel. The effect on downstream reaches due to the removal of obstructions shall be analyzed using standard stream and channel geomorphologic procedures. The removal of sand and gravel deposits from within the stream channel shall be in compliance with the State of Idaho, “Rules and regulations and Minimum Standards for Stream Channel Alterations”.

If clearing and snagging will result in streambank erosion, Practice Standard (580), Streambank

and Shoreline Protection will be used in conjunction with this standard.

All areas denuded and disturbed during snag removal shall be restored by planting native vegetation where practical. Disturbance of wetlands, riparian areas, and fish and wildlife habitat sites shall be minimized or avoided where possible.

CONSIDERATIONS

Special attention should be given to restoring, maintaining or improving landscape resources and habitat for fish and wildlife, where applicable.

Effects on water quantity and quality should be considered.

Removal of deadfalls, stumps, and trees from streambanks and channels will increase discharge, velocity and channel capacity that may reduce flood damage from out of bank flow. Improved flow conditions will lower hydraulic gradient and drain flood plains more quickly. Rapid drawdown may cause sloughing of saturated, unstable streambanks.

Decreased groundwater recharge in water losing streams will result from reduced residence time of water in the channel.

Temporary losses of aquatic or wetland habitat may occur with the removal of vegetation.

Channel instability could increase sediment yield from bank erosion until re-vegetated.

During implementation of the practice, there may be increased turbidity due to an increased sediment load. Water quality may be further degraded by chemical substances (i.e., nitrogen or phosphorus) attached to the sediment particles.

During construction, a heavy organic load may be produced resulting in a decreased availability of dissolved oxygen. Long term effects may cause a decrease in yields of sediment and sediment attached substances.

Increased surface water temperatures, at low flow, may occur from removal of shade producing canopy until re-growth occurs. Accelerated flows may reduce the period of time water is exposed for "sun warming", thus reducing water temperature.

In streams carrying dissolved substances, a reduction in ground water recharge may contribute to improved aquifer quality.

The number of pools and riffles forming the channel bottom may be reduced and fish habitat could be adversely affected.

Measures and construction methods that enhance fish and wildlife values should be incorporated as needed and practical. Special attention should be given to landscape aesthetics, protecting and maintaining key shade, food, and den trees and to stabilization of disturbed areas.

Consider removal methods and disposal location of cleared material that will not be used for bioengineering (removal from site, placement in or out of the floodplain, not placed in wetland areas), and implement according to permits conditions.

PLANS AND SPECIFICATIONS

Plans and specifications for clearing and snagging shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose(s).

Construction operations shall be carried out in a manner and sequenced so that impacts on the environment will be minimized and held within acceptable limits.

All operations shall be carried out in a safe and skillful manner. Safety and health regulations shall be observed and appropriate safety measures used.

OPERATION AND MAINTENANCE

A maintenance program shall be established by the landowner/user to maintain capacity and vegetative cover. Items to consider are:

- Control grazing in the construction area during vegetative establishment and when soil conditions are wet.
- Fertilize as needed to maintain a vigorous vegetative cover.
- Promptly repair eroded areas.
- Remove major silt and sediment accumulations in the channel cross-section

as soon as practical, when the effects are causing significant bank erosion problems.

- Re-establish vegetation cover immediately where scour erosion has removed established seeding.
- Keep inlets to side drainage structures and channels open and armor if necessary.
- Periodically inspect the area for signs of significant stream bank undermining or instability.
